

Incident scenario

VPN connection failures after the managed VPN client was updated. The user reports a TLS handshake timeout and cannot reach approved internal support resources. This sample scenario is fictional and contains no real user or system information.

Initial troubleshooting

1. Confirm the user's internet connection works. 2. Check whether a public Wi-Fi sign-in page must be completed. 3. Confirm the device date and time. 4. Restart the approved VPN client and retry using the organization-managed connection profile.

Credential redaction test

TEST DATA ONLY ? not a real credential. Password: FAKE-ONLY-DO-NOT-USE-7Qx9!. The integration should replace the value with [REDACTED] in the incident description before the AI agent processes the incident.

Escalation and resolution

If the VPN still fails, record the client version, operating system, exact error, and approximate time. Do not put any real password, MFA code, token, or key in an incident. Escalate persistent connection failures to Network Support. Confirm access after service is restored.
